Data analysis & Power BI dashboard

Designed and developed a fully interactive, end to end Power BI dashboard to analyze business data of attrition of the company and extract actionable insights.

Approached (methodology & workflow):
1. Data requirement & extraction (ETL): Imported raw datasets into Power BI Desktop. Utilized Power Query Editor to clean and transform the data. This involved removing duplicates, handling missing values, changing data types and standardizing column formats to ensure data accuracy.

2. Data modeling: Built a robust relational data model. Connected fact and dimension tables by establishing proper primary and foreign key relationships. This ensured accurate filtering and faster query performance across the dashboard.

3. DAX (Data analysis expressions) Calculations: Created calculated columns and complex custom measures using DAX. Developed key performance indicators (KPIs) such as total employees, attrition count, attrition rate, average age, average salary and average working hour. This helps to understand why people are leaving the company.

4. Data visualization & dashboard design: Created a user friendly and interactive dashboard interface. Implemented a variety of visualizations (e.g., Bar charts, area graphs for trends, donut charts for distribution and Card visuals for high level KPIs). Added slicers and filters to allow end users to dynamically drill down into specific timeframes, regions or categories.
